Efficient Training

Introduction

Training large models takes a significant amount of computing time, and most of it is spent on d **most of it** *ata that the model has already learned well. We show a* simple schedule that skips such examples and halves the cost while keeping the accuracy of the full run.

- Skip examples the model already knows.
- Keep a small sample of them for checking.
  - Never skip the rare classes.

Method

1. Score every example.
2. Drop the easiest third.
3. Train on the rest.

Model	Hours	Accuracy
Baseline	120	91.2
Ours	61	91.0

Table 1. Training cost and accuracy.

Results

Training large models takes a significant amount of computing time, and most of it is spent on data that the model has already learned well. We show a simple schedule that skips such examples and halves the cost while keeping the accuracy of the full run.

```
def skip(score):
return score < 0.1
```

The schedule is short, and it works with any optimiser.
