Efficient Training of Language Models

October 24, 2026

1 Introduction

In recent years, deep learning has had an impact on a wide range of fields, as shown in [**?**]. However, training large models requires a significant amount of computational resources. In order to address this problem, we propose a simple method that reduces the cost of training by 50% while maintaining accuracy.

Our approach plays an important role in making research more accessible. The results clearly demonstrate that the method works on all benchmarks (see Table **??**).

$$L(\theta) = -\sum_{i=1}^{N} \log p_\theta(x_i) \tag{1}$$

2 Method

We carefully analyse the loss $L(\theta)$ and **significantly** reduce the number of gradient steps. It is important to note that this does not require any additional data.
